August 17, 2021

This document compares emission estimates from the v_2021_4_21 pre-release of the Community Emissions Data System (CEDS) with values from the CMIP6 release (v_2016_07_16).

For a list of changes and updates see the [release notes](#).

Comments are welcome. The best way to comment is through the [CEDS Issues](#) page. Known issues with this data will noted there.

Previous [versions of this set of comparison figures](#) can be used to trace changes through CEDS versions.

For additional information on CEDS and this data system release, please see <https://github.com/JGCRI/CEDS>.

The largest global changes since the CMIP6 release (v_2016_07_16) are:

- Lower BC and OC after about 1990
- Overall lower NMVOC (lower ENE, offset partially after 1985 by higher SLV)
- Lower NO_x (India transport) and SO₂ (China Industry) after 2010
- Higher CH₄ before 1990 (higher from Africa and Middle East, offset after 1990 by lower China)

Some of the major updates:

- Updated IEA energy data
- Use of updated EDGAR, GAINS, and country inventories
- Updated industrial BC/OC/SO₂ emissions for China, particularly BC/OC from coke production
- Improved trends for emissions from petroleum production over time
- Lower assumed biomass consumption in Nigeria and Ethiopia
- Lower emissions from open burning of residential waste in most lower income regions
- Calibration of NO₂, CO, NMVOC (and SO₂) India emissions to GAINS

The newer IEA data has much lower biomass consumption after 2000 in China, lowering BC and OC emissions. Updated assumptions for industrial BC and OC emissions in China also lowered emission estimates in recent years (see [release notes](#)). EDGAR v5 also has lower NMVOC emissions from the energy sector, which are the values used for most of Africa, Middle East, and South America.

The comparison graphs were updated as of 08/17/2021 to correct an error in the comparisons. This correction only impacted the comparison graphs here, not the underlying data.
